

CSE 130 Programming Languages

Datatypes

Ranjit Jhala
UC San Diego

Recap: ML's Holy Trinity

1. Programmer enters expression
2. ML checks if expression is “well-typed”
 - Using a precise set of rules, ML tries to find a unique type for the expression meaningful type for the expr
3. ML evaluates expression to compute value
 - Of the same “type” found in step 2

Story So Far...

- Simple Expressions
- Branches
- Let-Bindings ...

- Today:
 - Finish Crash Course
 - Datatypes

Next: functions, but remember ...

Everything is an expression
Everything has a value
Everything has a type

A function is a value!

A shorthand for function binding

```
# let neg = fun f -> fun x -> not (f x);  
...  
# let neg f x = not (f x);  
val neg : int -> int -> bool = fn  
  
# let is5gte = neg is5lt;  
val is5gte : int -> bool = fn;  
# is5gte 10;  
val it : bool = false;  
# is5gte 2;  
val it : bool = true;
```

Put it together: a “filter” function

If arg “matches”
this pattern... ..then use
this Body Expr

```
- let rec filter f xs =  
  match xs with  
  | [] -> []  
  | (x::xs') -> if f x  
                 then x::(filter f xs')  
                 else (filter f xs');
```

```
val filter : ('a->bool)->'a list->'a list = fn
```

```
# let list1 = [1;31;12;4;7;2;10];;
```

```
# filter is5lt list1 ;;
```

```
val it : int list = [31;12;7;10]
```

```
# filter is5gte list1;;
```

```
val it : int list = [1;4;2]
```

```
# filter even list1;;
```

```
val it : int list = [12;4;2;10]
```

Put it together: a “partition” function

```
# let partition f l = (filter f l, filter (neg f) l);  
fn val partition : ('a->bool)->'a list->'a list * 'a list =  
  
# let list1 = [1,31,12,4,7,2,10];  
- ...  
# partition is5lt list1 ;  
val it : (int list * int list) = ([31,12,7,10],[1,2,10])  
  
# partition even list1;  
val it : (int list * int list) = ([12,4,2,10],[1,31,7])
```

A little trick ...

```
# 2 <= 3;; ...
val it : bool = true
# "ba" <= "ab";;
val it : bool = false

# let lt = (<) ;;
val it : 'a -> 'a -> bool = fn

# lt 2 3;;
val it : bool = true;
# lt "ba" "ab" ;;
val it : bool = false;

# let is5Lt = lt 5;
val is5lt : int -> bool = fn;
# is5lt 10;
val it : bool = true;
# is5lt 2;
val it : bool = false;
```

Put it together: a “quicksort” function

```
let rec sort xs =  
  match xs with  
  | []      -> []  
  | (h::t) -> let (l,r) = partition ((<) h) t in  
               (sort l)@(h::(sort r))
```

Now, lets begin at the beginning ...

News

- Ocaml-top issues?
- Please post questions to Piazza
- Seating: Don't Worry!

What about more complex data ?

Many kinds of expressions:

1. Simple
2. Variables
3. Functions

What about more complex data ?

- We've seen some **base** types and values:
 - Integers, Floats, Bool, String etc.
- Some ways to **build** up types:
 - Products (tuples), records, “lists”
 - Functions
- Design Principle: **Orthogonality**
 - Don't clutter **core language** with stuff
 - Few, powerful orthogonal building techniques
 - Put “**derived**” types, values, functions in **libraries**

What about more complex data ?

- We've seen some **base** types and values:
 - Integers, Floats, Bool, String etc.
- Some ways to **build** up types:
 - Products (tuples), records, “lists”
 - Functions

Next: Building datatypes

Three key ways to build complex types/values

1. “Each-of” types

Value of T contains value of T1 **and** a value of T2

2. “One-of” types

Value of T contains value of T1 **or** a value of T2

3. “Recursive”

Value of T contains (sub)-value of **same type T**

Next: Building datatypes

Three key ways to build complex types/values

1. “Each-of” types **(T1 * T2)**

Value of T contains value of T1 **and** a value of T2

2. “One-of” types

Value of T contains value of T1 **or** a value of T2

3. “Recursive”

Value of T contains (sub)-value of **same type T**

Suppose I wanted ...

... a program that processed lists of attributes

- Name (string)
- Age (integer)
- DOB (int-int-int)
- Address (string)
- Height (float)
- Alive (boolean)
- Phone (int-int)
- email (string)

Many kinds of attributes (too many to put in a record)

- can have multiple names, addresses, phones, emails etc.

Want to store them in a **list**. Can I ?

Suppose I wanted ...

Attributes:

- Name (string)
- Age (integer)
- DOB (int-int-int)
- Address (string)
- Height (real)
- Alive (boolean)
- Phone (int-int)
- email (string)

```
type attrib =  
    Name of string  
| Age of int  
| DOB of int*int*int  
| Address of string  
| Height of float  
| Alive of bool  
| Phone of int*int  
| Email of string;;
```

Quiz: Here is a typedef ...

```
type attrib = Name of string
             | Age   of int
             | Height of float
```

What is the type of: **Name “Tony Stark”**

- (a) Syntax Error
- (b) Type Error
- (c) **string**
- (d) **attrib**
- (e) 'a

Constructing Datatypes

```
type t = C1 of t1 | C2 of t2 | ... | Cn of tn
```

t is a new datatype.

A value of type t is either:

a value of type $t1$ placed in a box labeled $C1$

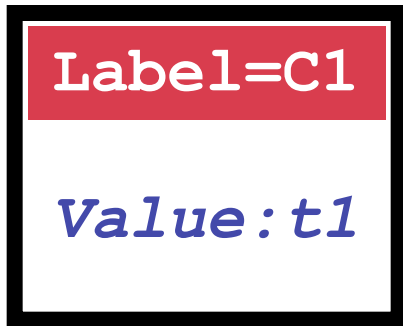

Or a value of type $t2$ placed in a box labeled $C2$

Or ...

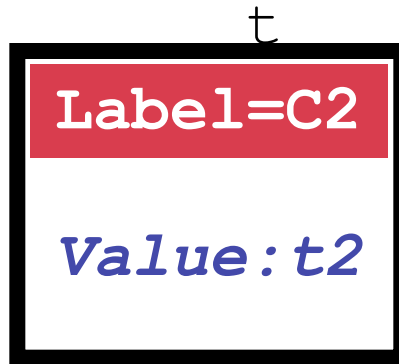

Or a value of type tn placed in a box labeled Cn

Constructing Datatypes

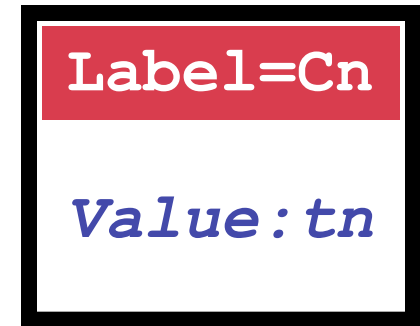

```
type t = C1 of t1 | C2 of t2 | ... | Cn of tn
```

OR

OR

All have the type **t**

How to PUT values into box?

Question: Here is a typedef ...

```
type attrib = Name of string  
           | Age of int  
           | Height of float
```

What is the type of: **Age “Tony Stark”**

- (a) Syntax Error
- (b) Type Error
- (c) **string**
- (d) **attrib**
- (e) 'a

How to PUT values into box?

How to create values of type `attrib` ?

```
# let a1 = Name "Ranjit";;  
val x : attrib = Name "Ranjit"  
# let a2 = Height 5.83;;  
val a2 : attrib = Height 5.83  
# let year = 1977 ;;  
val year : int = 1977  
# let a3 = DOB (9,8,year) ;;  
val a3 : attrib = DOB (9,8,1977)  
# let a_list = [a1;a2;a3];;  
val a_list : attrib list = ...
```

```
type attrib =  
    Name of string  
| Age of int  
| DOB of int*int*int  
| Address of string  
| Height of float  
| Alive of bool  
| Phone of int*int  
| Email of string;;
```

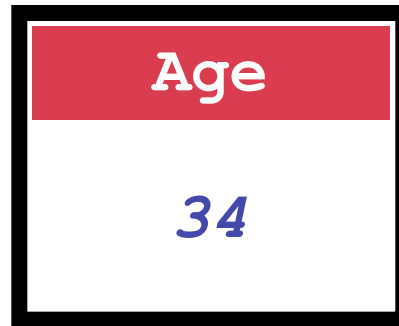

Constructing Datatypes

```
type attrib
```

```
= Name of string      | Age of int          | DOB of int*int*int  
| Address of string  | Height of float   | Alive of bool  
| Phone of int*int   | Email of string;;
```

OR

OR

```
Name "Ranjit"
```

```
Age 34
```

```
DOB (9, 8, 77)
```

All have type **attrib**

One-of types

- We've defined a “one-of” type named `attrib`
- Elements are **one of**:
 - `string`,
 - `int`,
 - `int*int*int`,
 - `float`,
 - `bool ...`

```
datatype attrib =  
    Name of string  
  | Age of int  
  | DOB of int*int*int  
  | Address of string  
  | Height of real  
  | Alive of bool  
  | Phone of int*int  
  | Email of string;
```

- Can create uniform `attrib` lists
- Say I want a function to print attribs...

Question: Here is a typedef ...

```
type attrib = Name of string
            | Age of int
            | Height of float
```

What is the type of:

```
[Name "Ranjit"; Age 35; Dob(9,8,77)]
```

- (a) Syntax Error
- (b) Type Error
- (c) `string * int * (int*int*int) list`
- (d) `'a list`
- (e) `attrib list`

How to TEST & TAKE whats in box?

Is it a ...
string?

or an
int?

or an
int*int*int?

or ...

How to TEST & TAKE whats in box?

Look at TAG!

Question: Here is a typedef ...

```
type attrib = Name of string | Age of int | ...
```

What does this evaluate to?

```
let welcome a = match a with  
                | Name s -> s  
in welcome (Name "Ranjit")
```

- (a) **Name "Ranjit" : 'a**
- (b) Type Error
- (c) **Name "Ranjit" : attrib**
- (d) **"Ranjit" : string**
- (e) Runtime Error

How to tell whats in the box ?

```
type attrib =  
  Name of string  
| Age of int  
| DOB of int*int*int  
| Address of string  
| Height of float  
| Alive of bool  
| Phone of int*int
```

```
match e with  
| Name s      -> ...(*s: string *)  
| Age i       -> ...(*i: int *)  
| DOB(d,m,y)-> ...(*d: int,m: int,y: int*)  
| Address a   -> ...(*a: string*)  
| Height h    -> ...(*h: int *)  
| Alive b     -> ...(*b: bool*)  
| Phone(y,r)-> ...(*a: int, r: int*)
```

Pattern-match expression: check if e is of the form ...

- On match:
 - value in box bound to pattern variable
 - matching result expression is evaluated
- Simultaneously test and extract contents of box

How to tell whats in the box ?

```
match e with
| Name s      -> printf "%s" s
| Age i       -> printf "%d" i
| DOB(d,m,y) -> printf "%d/%d/%d" d m y
| Address s   -> printf "%s" s
| Height h    -> printf "%f" h
| Alive b     -> printf "%b" b s
| Phone(a,r)  -> printf "(%d)-%d" a r
```

Pattern-match expression: check if e is of the form ...

- On match:
 - value in box bound to pattern variable
 - matching result expression is evaluated
- Simultaneously test and extract contents of box

Question: Here is a typedef ...

type attrib = Name of string | Age of int | ...

What does this evaluate to?

let welcome a = match a with

 | Name s -> s

 in welcome (Age 34)

- (a) **Name "Ranjit" : `a**
- (b) **Type Error**
- (c) **Name "Ranjit" : attrib**
- (d) **"Ranjit" : string**
- (e) **Runtime Error**

How to tell whats in the box

```
# match (Name "Ranjit") with
| Name s -> printf "Hello %s\n" s
| Age i   -> printf "%d years old" i
;;
```

```
Hello Ranjit
- : unit = ()
```

First case matches the tag (Name)

Evals branch with **s** “bound” to string contents

How to TEST & TAKE whats in box?

BEWARE!!

Be sure to
handle all
TAGS!

Beware! Handle All TAGS!

```
# match (Name "Ranjit") with
| Age i    -> Printf.printf "%d" i
| Email s  -> Printf.printf "%s" s
;;
```

Exception: Match Failure!!

None of the cases matched the tag (Name)
Causes nasty *Run-Time Error*

Compiler To The Rescue!!

```
# let printAttrib a =  
  match a with  
  | Name s -> Printf.printf "%s" s  
  | Age i   -> Printf.printf "%d" i  
  | DOB (d,m,y) -> Printf.printf "%d / %d / %d" d m y  
  | Address addr -> Printf.printf "%s" addr  
  | Height h -> Printf.printf "%f" h  
  | Alive b -> Printf.printf "%b" b  
  | Email e -> Printf.printf "%s" e  
  ;;
```

Warning P: this pattern-matching is not exhaustive.
Here is an example of a value that is not matched:
Phone (_, _)

Compile-time checks for:

missed cases: ML warns if you **miss** a case!

Q: What does this evaluate to ?

```
type attrib = Name of string | ...
```

```
let welcome a = match a with
```

```
    | Name s -> "Hello!" ^ s
```

```
    | Name s -> "Welcome!" ^ s
```

```
in welcome (Name "Mickey")
```

(a) Type Error

(b) `"Welcome!Mickey" : string`

(c) Runtime Error

(d) `"Hello!Mickey" : string`

(e) `"Hello!MickeyWelcome!Mickey"Ranjit" : string`

Compiler To The Rescue!!

```
# let printAttrib a =  
  match a with  
    Name s -> Printf.printf "%s" s  
  | Age i   -> Printf.printf "%d" i  
  | DOB (d,m,y) -> Printf.printf "%d / %d / %d" d m y  
  ...  
  | Age i -> Printf.printf "%d" i  
;;
```

Warning U: this match case is unused.

Compile-time checks for:

redundant cases: ML warns if a case never matches

Benefits of `match-with`

```
match e with
  C1 x1 -> e1
| C2 x2 -> e2
| ...
| Cn xn -> en
```

```
type t =
  C1 of t1
| C2 of t2
| ...
| Cn of tn
```

1. Simultaneous `test-extract-bind`
2. Compile-time checks for:
 - `missed` cases: ML warns if you `miss` a `t` value
 - `redundant` cases: ML warns if a case `never` matches

match-with is an Expression

```
match e with
  C1 x1 -> e1
| C2 x2 -> e2
| ...
| Cn xn -> en
```

Q: What does this evaluate to ?

```
type attrib = Name of string | Age of int | ...
```

```
let welcome a = match a with
```

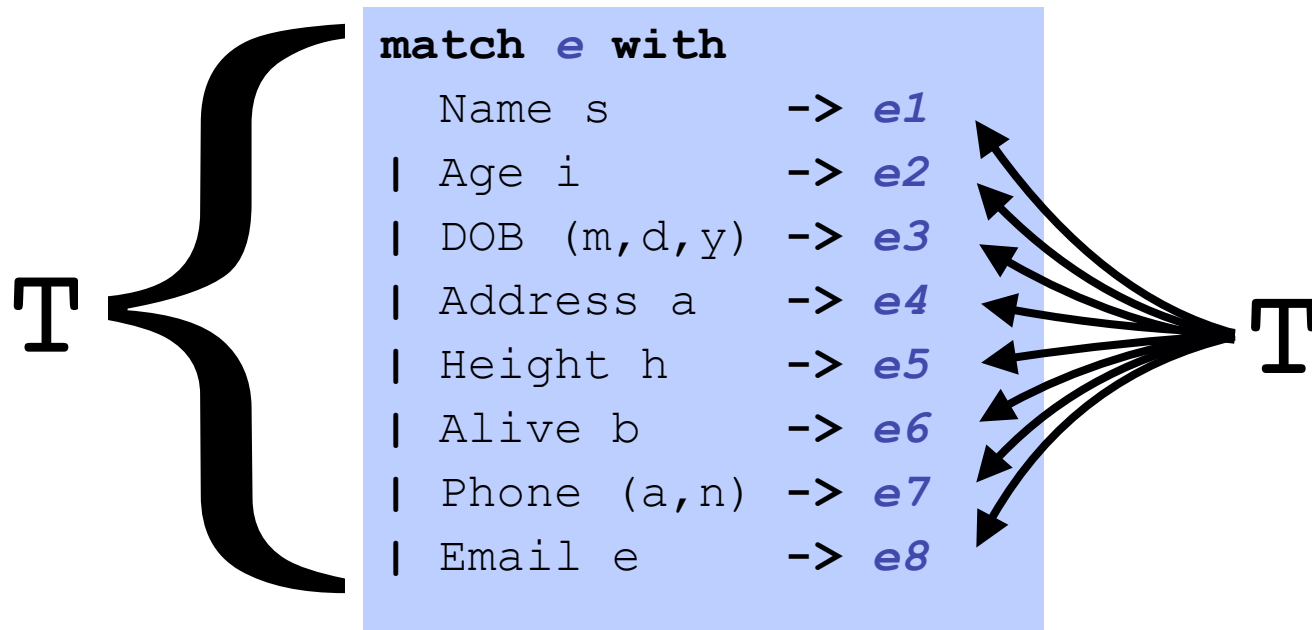

```
    | Name s -> s
```

```
    | Age i -> i
```

```
in welcome (Name "Ranjit")
```

- (a) **"Ranjit" : string**
- (b) Type Error
- (c) **Name "Ranjit" : attrib**
- (d) Runtime Error

match-with is an Expression

Type Rule

- e_1, e_2, \dots, e_n must have same type \mathbb{T}
- Type of whole expression is \mathbb{T}

Next: Building datatypes

Three key ways to build complex types/values

1. “Each-of” types **t1 * t2**

Value of T contains value of T1 **and** a value of T2

2. “One-of” types **type t = C1 of t1 | C2 of t2**

Value of T contains value of T1 **or** a value of T2

3. “Recursive” type

Value of T contains (sub)-value of **same type T**

“Recursive” types

```
type nat = Zero | Succ of nat
```

“Recursive” types

```
type nat = Zero | Succ of nat
```

Wait a minute! **Zero** of what ?!

“Recursive” types

```
type nat = Zero | Succ of nat
```

Wait a minute! **Zero** of what ?!

Relax.

Means “empty box with label **Zero**”

“Recursive” types

```
type nat = Zero | Succ of nat
```

What are values of `nat` ?

“Recursive” types

```
type nat = Zero | Succ of nat
```

What are values of `nat` ?

Zero

“Recursive” types

```
type nat = Zero | Succ of nat
```

What are values of `nat` ?

One `nat` contains another!

“Recursive” types

```
type nat = Zero | Succ of nat
```

What are values of `nat` ?

One `nat` contains another!

“Recursive” types

```
type nat = Zero | Succ of nat
```

What are values of `nat` ?

One `nat` contains another!

“Recursive” types

```
type nat = Zero | Succ of nat
```

What are values of `nat` ?
One `nat` contains another!

`nat` = recursive type

Inductive Expression

Next: Lets get cosy with Recursion

Recursive Code Mirrors Recursive Data

Lists are recursive types!

```
type int_list =  
  Nil  
| Cons of int * int_list
```

Think about this! What are values of `int_list` ?

`Cons(1,Cons(2,Cons(3,Nil)))`

`Cons(2,Cons(3,Nil))`

`Cons(3,Nil)`

`Nil`

Lists aren't built-in !

```
datatype int_list =  
  Nil  
| Cons of int * int_list
```

Lists are a **derived** type: built using elegant core!

1. Each-of
2. One-of
3. Recursive

`::` is just a pretty way to say “Cons”

`[]` is just a pretty way to say “Nil”

Some functions on Lists : Length

```
let rec len l =  
  match l with  
  Nil -> 0  
  | Cons (_, t) -> 1 + (len t)
```

Matches everything, no binding

```
let rec len l =  
  match l with  
  Cons (_, t) -> 1 + (len t)  
  | _ -> 0
```

Pattern-matching in order

- Must match with `Nil`

Some functions on Lists : Append

- Find the right **induction** strategy
 - **Base** case: pattern + expression
 - **Induction** case: pattern + expression

Well designed datatype gives strategy

null, hd, tl are all functions ...

Bad ML style: More than aesthetics !

Pattern-matching better than test-extract:

- ML checks all cases covered
- ML checks no redundant cases
- ...at compile-time:
 - fewer errors (crashes) during execution
 - get the bugs out ASAP!

Some functions on Lists : Max

- Find the right **induction** strategy
 - **Base** case: pattern + expression
 - **Induction** case: pattern + expression

Well designed datatype gives strategy

Next: Lets get cosy with Recursion

Recursive Code Mirrors Recursive Data

Q: How is this tree represented ?

```
type tree =  
| Leaf of int  
| Node of tree*tree
```

- (a) (1, 2), 3
- (b) (Leaf 1, Leaf 2), Leaf 3
- (c) Node (Node (Leaf 1, Leaf 2), Leaf 3)
- (d) Node ((Leaf 1, Leaf 2), Leaf 3)
- (e) None of the above

Representing Trees

```
type tree =  
| Leaf of int  
| Node of tree*tree
```

Leaf 1

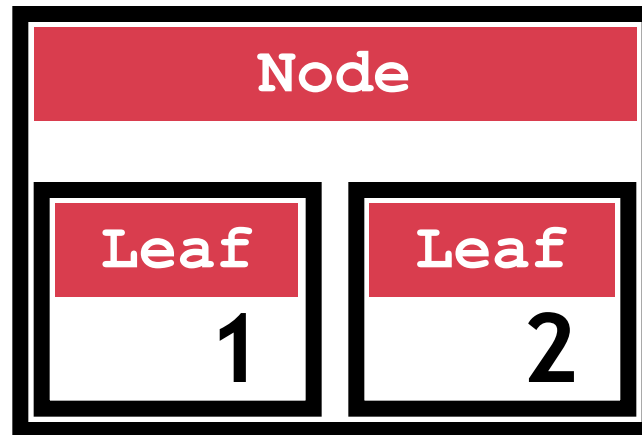

Representing Trees

```
type tree =  
| Leaf of int  
| Node of tree*tree
```

Leaf 2

Representing Trees

```
type tree =  
| Leaf of int  
| Node of tree*tree
```

Node(Leaf 1, Leaf 2)

Representing Trees

```
type tree =  
| Leaf of int  
| Node of tree*tree
```

Leaf 3

Representing Trees

```
type tree =  
| Leaf of int  
| Node of tree*tree
```

`Node(Node(Leaf 1, Leaf 2), Leaf 3)`

Representing Trees

```
type tree =  
| Leaf of int  
| Node of tree*tree
```

```
Node(Node(Leaf 1, Leaf 2), Leaf 3)
```

Next: Lets get cosy with Recursion

Recursive Code Mirrors Recursive Data

Q: What does this evaluate to ?

```
let rec foo t = match t with
| Leaf n          -> 1
| Node (t1, t2)  -> foo t1 + foo t2
```

```
foo (Node(Node(Leaf 1,Leaf 2),Leaf 3))
```

- (a) **Type Error**
- (b) **1 : int**
- (c) **3 : int**
- (d) **6 : int**

sum_leaf: tree -> int

“Sum up the leaf values”. E.g.

```
# let t0 = Node(Node(Leaf 1, Leaf 2), Leaf 3);;  
# sum_leaf t0 ;;  
- : int = 6
```

`sum_leaf: tree -> int`

```
type tree =  
| Leaf of int  
| Node of tree*tree
```

```
let rec sum_leaf t =
```

sum_leaf: tree -> int

```
type tree =
```

Base pattern

```
| Leaf of int
```

Inductive pattern

```
| Node of tree*tree
```

```
let rec sum_leaf t =
```

`sum_leaf: tree -> int`

```
type tree =
```

Base pattern | **Leaf** of int

Inductive pattern | **Node** of tree*tree

```
let rec sum_leaf t =
```

```
match t with
```

Base pattern | **Leaf n** ->

Inductive pattern | **Node(t1, t2)** ->

sum_leaf: tree -> int

```
type tree =
```

Base pattern

```
| Leaf of int
```

Inductive pattern

```
| Node of tree*tree
```

```
let rec sum_leaf t =
```

```
match t with
```

Base pattern

```
| Leaf n -> n Base Expression
```

Inductive pattern

```
| Node(t1, t2) -> sum_leaf t1 + sum_leaf t2
```

Inductive Expression

Recursive Code Mirrors Recursive Data

Code almost writes itself!

Another Example: Calculator

Want an arithmetic calculator to evaluate expressions like:

- $4.0 + 2.9$
- $3.78 - 5.92$
- $(4.0 + 2.9) * (3.78 - 5.92)$

Another Example: Calculator

Want an arithmetic calculator to evaluate expressions like:

- $4.0 + 2.9 \implies 6.9$
- $3.78 - 5.92 \implies -2.14$
- $(4.0 + 2.9) * (3.78 - 5.92) \implies -14.766$

Whats a ML **TYPE** for **REPRESENTING** expressions ?

Another Example: Calculator

Want an arithmetic calculator to evaluate expressions like:

- $4.0 + 2.9 \implies 6.9$
- $3.78 - 5.92 \implies -2.14$
- $(4.0 + 2.9) * (3.78 - 5.92) \implies -14.766$

Whats a ML **TYPE** for **REPRESENTING** expressions ?

```
type expr =  
| Num of float  
| Add of expr*expr  
| Sub of expr*expr  
| Mul of expr*expr
```

Another Example: Calculator

Want an arithmetic calculator to evaluate expressions like:

- $4.0 + 2.9 \implies 6.9$
- $3.78 - 5.92 \implies -2.14$
- $(4.0 + 2.9) * (3.78 - 5.92) \implies -14.766$

Whats a ML **FUNCTION** for **EVALUATING** expressions ?

```
type expr =  
| Num of float  
| Add of expr*expr  
| Sub of expr*expr  
| Mul of expr*expr
```

Another Example: Calculator

Want an arithmetic calculator to evaluate expressions like:

- $4.0 + 2.9 \implies 6.9$
- $3.78 - 5.92 \implies -2.14$
- $(4.0 + 2.9) * (3.78 - 5.92) \implies -14.766$

Whats a ML **FUNCTION** for **EVALUATING** expressions ?

```
type expr =  
| Num of float  
| Add of expr*expr  
| Sub of expr*expr  
| Mul of expr*expr
```

Another Example: Calculator

Want an arithmetic calculator to evaluate expressions like:

- $4.0 + 2.9 \implies 6.9$
- $3.78 - 5.92 \implies -2.14$
- $(4.0 + 2.9) * (3.78 - 5.92) \implies -14.766$

Whats a ML **FUNCTION** for **EVALUATING** expressions ?

```
type expr =  
| Num of float  
| Add of expr*expr  
| Sub of expr*expr  
| Mul of expr*expr
```

```
let rec eval e = match e with  
| Num f      ->  
| Add (e1, e2) ->  
| Sub (e1, e2) ->  
| Mul (e1, e2) ->
```

Another Example: Calculator

Want an arithmetic calculator to evaluate expressions like:

- $4.0 + 2.9 \implies 6.9$
- $3.78 - 5.92 \implies -2.14$
- $(4.0 + 2.9) * (3.78 - 5.92) \implies -14.766$

Whats a ML **FUNCTION** for **EVALUATING** expressions ?

```
type expr =  
| Num of float  
| Add of expr*expr  
| Sub of expr*expr  
| Mul of expr*expr
```

```
let rec eval e = match e with  
| Num f      -> f  
| Add (e1,e2) -> eval e1 +. eval e2  
| Sub (e1,e2) -> eval e1 -. eval e2  
| Mul (e1,e2) -> eval e1 *. eval e2
```
